Informed Trading in the Stock Market and Option Price Discovery

Abstract

When activist shareholders file Schedule 13D filings, the average excess return on target stocks is 6% and stock price volatility drops by about 10%. Prior to filing days, volatility (price) information is reflected in option (stock) prices. Using a comprehensive sample of trades by Schedule 13D filers which reveals on what days and in what markets they trade prior to filing Schedule 13D, we show that on days when activists accumulate *shares*, option implied volatility decreases, volatility skew increases, and option bid-ask spreads widen. The adverse selection risk in options is driven by the volatility component of private information and is higher when stock and option markets are highly integrated. The evidence is consistent with informed trading in the stock market contributing to the flow of volatility information into option prices.

It has long been argued that derivative markets should provide an interesting trading avenue for investors to exploit an informational advantage. Options may provide valuable embedded leverage for example (Black, 1975). They may also allow investors to achieve better liquidity or to hide their information better (Back, 1993; Biais and Hillion, 1994; Easley et al., 1998). Indirect empirical evidence that informed trading does occur in option markets based on the predictability of stock returns by option to stock volume or other option market statistics has been documented (Vijh, 1990; Chan et al., 2002; Chakravarty et al., 2004; Pan and Poteshman, 2006). On the other hand, Muravyev et al. (2013) suggest that no economically significant price discovery occurs in the option market. Thus, whether informed investors actually use options and what informational linkages there are between option and stock markets remain open questions.

In this paper we use new data on informed investors' trading behavior to revisit the following questions. How do investors who possess valuable private information trade in stocks and derivatives? How does private information flow into stock and option prices? Do measures of adverse selection in option and stock markets respond to the presence of informed trading?

Addressing these questions is challenging because the identity of informed investors is typically unobservable to econometricians. Standard approaches in the literature to overcome this challenge include studying periods of time when informed trading is likely (e.g., M&A announcements) or assuming that a class of investors is informed (e.g., corporate insiders or institutional investors).

In this paper we use a data set of trades by investors who we can identify as having substantial private information to study how private information flows into stock and option prices. More specifically, we follow Collin-Dufresne and Fos (2015) and exploit a disclosure requirement Rule 13d-1(a) of the 1934 Securities Exchange Act to identify trades that rely on valuable private information. Rule 13d-1(a) requires investors to file with the SEC within 10 days of acquiring more than 5% of any class of securities of a

publicly traded company if they have an interest in influencing the management of the company. In addition to having to report their actual position at the time of filing, Item 6 of Schedule 13D requires the filer to disclose whether or not derivative contracts have been used. Moreover, Item 5(c) of Schedule 13D requires the filer to report the date, price, and quantity of all trades in the target company executed during the 60 days that precede the filing date.¹ Thus, we not only know when Schedule 13D filers trade, but also what market (stock vs option) they participate in.

We document several new facts. First, we find that Schedule 13D filers trades contain information about both the direction and the volatility of future stock returns. An average Schedule 13D filing in our sample is characterized by a positive and significant market reaction upon announcement. For example, the cumulative return in excess of the market is about 6% in the $(t-10,t+1)$ window around the filing date. Moreover, stock price volatility drops by about 10% after the filing date. Whereas stock price implications of Schedule 13D filings have been studied (e.g., Brav et al., 2008; Collin-Dufresne and Fos, 2015), the evidence on the changes in realized volatility is novel.²

Second, we show that both directional and volatility information is reflected in stock and option prices prior to Schedule 13D filing days. When we consider stock prices, we find that about half of the directional private information is reflected in stock prices prior to the schedule 13D filing public announcement date. The results are even stronger for volatility. We find that implied volatilities decline closer to the filing date, suggesting that option prices anticipate the future drop in realized volatility after the filing date. In

¹To quote from Item 5(c), filers have to “...describe any transactions in the class of securities reported on that were effected during the past sixty days or since the most recent filing of Schedule 13D, whichever is less...”

²Note that, by its very nature, the information held by Schedule 13D filers is likely to qualify as “private information” and to be long-lived. Collin-Dufresne and Fos (2014) develop a theoretical model in which activist shareholders can expend effort and change firm value. In that model the market price depends on the market maker’s estimate of the activist’s share ownership, since the latter determines the effort level of the informed trader, and hence the liquidation value of the firm. This model shows that a significant part of the valuable private information pertains to the activist’s own holdings, which by definition is information known only to him.

fact, when we split the target firms into large (positive), average, and small (negative) future changes in realized volatility, we find that implied volatilities correctly track future realized volatilities in each sample. We further find that implied volatility smiles and time-slopes steepen substantially closer to the filing date, reflecting higher chances of a large informational event. Overall, these results indicate that stock and option prices reflect a substantial part of directional and volatility private information.

Third, we ask whether option bid-ask spreads indicate higher adverse selection risk. We find that option bid-ask spreads are *wider* closer to the filing date. Interestingly, when we double sort target firms based on the magnitude of the future stock return and of the future change in volatility, we find that the increase in option bid-ask spreads is driven by the target firms that experience a large future change in volatility. Moreover, we find that option market trading volume decreases for firms with large future changes in volatility. This suggests that option prices reflect the adverse selection risk associated with the volatility component of private information rather than the directional component.

Fourth, we exploit the unique feature of our data and study when and how Schedule 13D filers use derivatives. We find that Schedule 13D filers rarely use derivatives. Specifically, only in 66 out of 2,905 Schedule 13D filings we analyze do informed investors disclose the usage of derivatives. That is, in about 98% of cases Schedule 13D filers decide to trade exclusively in the stock market. This is despite the fact that Schedule 13D filers build economically significant positions: the average toehold held at the filing date is more than 7% of outstanding shares. This finding suggests that derivatives may not be that attractive for this class of informed traders and that they play a minor role in activists' trading strategies (consistent with the wider option market bid-ask spread and small trading volume). That said, we find that when exchange traded options are available then usage by activists increases (from 2% to 10% of cases). In that case, they use OTC derivatives in around 35% of cases and exchange-listed derivatives in around 65% of cases. Interestingly, they often use OTC derivatives to construct synthetic long forward

positions in order to avoid disclosure required under the Hart-Scott-Rodino (HSR) Act of 1976 (see Section IV for further details). When they do use derivatives then activists seek to increase their overall economic exposure to the stock (and not to hedge their risk). They achieve 2.3% long exposure (as measured by the percentage of outstanding shares) via derivatives and 6.4% via stocks, which together is 1.2% more than what they achieve when trading only stocks.

Finally, we study the role of informed trading in price discovery. In general, researchers do not observe trades by informed investors. The key advantage of our study is that we not only know when Schedule 13D filers trade, but also what market (stock vs option) they participate in. We show that when Schedule 13D filers trade in the *stock* market, directional private information flows into stock prices and volatility private information flows into option prices. To further sharpen the analysis, we restrict the sample to events when Schedule 13D filers did not use derivatives. A unique feature of this sample is that we know not only when informed activists trade in the underlying shares, but also that they do not participate in direct trading in derivatives. These features allow us to isolate the effect of informed trading in stock market on option prices. We find that the volatility information flows into option prices on days when Schedule 13D filers trade in the stock and even though they do not trade derivatives. The key implication is that market makers in the option market infer volatility information from trading activity and prices in the stock market. Supporting this interpretation, we find wider bid-ask spreads and smaller trading volumes in the option market closer to the filing date (when Schedule 13D filers are more likely to trade).

The paper is organized as follows. Section I presents the institutional background and describes the data. The magnitude and types of information asymmetry are analyzed in Section II. Section III shows that directional and volatility private information flows into stock and option prices. Section IV analysis how private information flows into prices. Finally, Section V concludes.

Related literature

The paper contributes to several strands of the literature.

First, the paper contributes to the literature that studies option markets around major corporate events. The literature considers M&A deals (e.g., Cao et al., 2005; Augustin et al., 2014), analyst revisions (e.g., Hayunga and Lung, 2014), stock splits (e.g., Gharghori et al., 2016), and illegal insider trading (e.g., Kacperczyk and Pagnotta, 2016). Whereas the exiting empirical literature on Schedule 13D filings is focused on stock price changes (e.g., Brav et al., 2008; Klein and Zur, 2009; Collin-Dufresne and Fos, 2015), our paper is the first to show that stock volatility drops around Schedule 13D filings. Moreover, we are the first to analyze the flow of directional and volatility private information into option prices around these events.

Second, the paper informs the literature that studies how information flows into option prices. As far as stock return predictability is concerned, Conrad et al. (2013) show that future stock returns are correlated with volatility skew, Johnson and So (2012) and Ge et al. (2015) show that future stock returns are correlated with option-to-stock volume, and Pan and Poteshman (2006) and Hu (2014) show that future stock returns are correlated with option order imbalance. Aragon and Martin (2012) show that institutional investors long positions in options predict both future stock returns and volatility and Ni et al. (2008) show that option order imbalance is correlated with future realized volatility. Our contribution is to show, using a unique feature of our data which provides information on when Schedule 13D filers trade in both stock and option markets, that information flows into option prices when Schedule 13D filers trade stocks.

Third, the paper contributes to literature that studies the relation between realized and future volatility. The existing literature suggests that implied volatility is a good forecast of future realized volatility (e.g., Poon and Granger, 2003). Our contribution is to show that implied volatility also forecasts private information events, such as Schedule 13D filings. A distinct feature of Schedule 13D filings is that the occurrence of the event is

controlled by the the informed trader—the Schedule 13D filer. That is, even though the mere occurrence of the informational event is Schedule 13D filer’s private information, option prices are informative about the timing of the event.

Finally, our paper contributes to the literature that studies the use of derivatives by activist shareholders.³ Theoretical literature suggests that activist shareholders may use derivatives to separate positions in a firm’s shares and votes (e.g., Brav and Mathews, 2011; Burkart and Lee, 2015). Christoffersen et al. (2007) document an active market for votes and document that the average vote sells for zero. Anecdotal evidence on the usage of derivative to decouple economic exposure and voting rights are reported by Hu and Black (2007). Our paper contributes to the literature by showing that Schedule 13D filers rarely use derivatives. Moreover, when activists do use derivatives, they seek to increase their overall economic exposure to the stock. Thus, our large sample evidence does not support the idea that derivatives are generally used to decouple economic exposure from voting rights.

I. Institutional Background and Sample Description

Rule 13d-1(a) of the 1934 Securities Exchange Act requires investors to file with the SEC within 10 days of acquiring beneficial ownership of more than 5% of a voting class of a company’s equity securities registered under Section 12 of the Securities Exchange Act of 1934. We refer to the date when the beneficial ownership crosses the 5% threshold as the ‘event date’ and to the date when the filing is sent to the SEC as the ‘filing date.’

³Whether or not activists use derivatives has important corporate governance implications and has attracted attention of academics as well as of practitioners. For example, in their petition for changing Section 13D, Wachtell, Lipton, Rosen & Katz argue that “*The increasing use of derivatives has accelerated the ability of investors to accumulate economic ownership of shares, usually with substantial leverage.*”. The full text of the petition is available at <http://www.sec.gov/rules/petitions/2011/petn4-624.pdf>.

Shares of common stock and options to purchase physical shares within 60 days are examples of equity securities that can trigger the filing. Because all exchange-listed derivatives in the United States are settled in physical delivery and are immediately exercisable, they count towards the computation of the 5% beneficial ownership threshold. In contrast, any instrument that is exclusively cash-settled or is not exercisable within 60 days does not. For example, any cash-settled over-the-counter (OTC) derivative agreement (options, equity swaps, etc.) will not result in beneficial ownership and therefore will not trigger a Schedule 13D filing. For example, a shareholder who owns 3% of common stock and cash-settled options that result in additional 4% of common stock exposure upon exercise is not required to file a Schedule 13D. Thus, whether a derivative security triggers a Schedule 13D filing depends crucially on the way the derivative is settled.

Item 6 of the Schedule 13D requires the filer to “*Describe any contracts, arrangements, understandings or relationships [...] with respect to any securities of the issuer, including but not limited to transfer or voting of any of the securities, finder’s fees, joint ventures, loan or option arrangements, puts or calls, guarantees of profits, division of profits or loss, or the giving or withholding of proxies, naming the persons with whom such contracts, arrangements, understandings or relationships have been entered into.*” Note that Item 6 covers all types of derivative contracts (settled in either physical or cash delivery). Thus, even if activists used non-traditional or cash-settled derivatives which do not count toward the 5% threshold, these positions have to be disclosed in Item 6 of the Schedule 13D filing. We therefore use Item 6 to identify whether a Schedule 13D filer uses derivatives.⁴

⁴The rule does not specify what information needs to be disclosed. It is up to the filer to decide the precision of the information she discloses. Therefore, we find substantial variation in the precision of disclosed information. Finally, note that all other items of Schedule 13D filing do not require disclosure of any information about derivatives as long as the subject security is common stock. Of course, it can be that the 5% threshold was crossed with a position in a derivative security only. In this case the derivative security is the “subject security” and therefore all items of Schedule 13D filing will have information about the derivative security (the subject security).

Information on trades executed by Schedule 13D filers is reported in Item 5(c). Item 5(c) of Schedule 13D requires the filer to report the date, price, and quantity of all trades in the underlying security (common stock) executed during the 60 days that precede the filing date.⁵

The sample of Schedule 13D filings with information on trades is constructed as follows.⁶ First, using an automatic search script, we identify 19,026 Schedule 13D filings from 1994 to 2010. The script identifies *all* Schedule 13D filings that appear on EDGAR. Next, we check the sample of 19,026 filings manually and identify events with information on trades. Since the trading characteristics of ordinary equities might differ from those of other assets, we retain only assets whose CRSP share codes are 10 or 11, that is, we discard certificates, ADRs, shares of beneficial interest, units, companies incorporated outside the U.S., Americus Trust components, closed-end funds, preferred stocks, and REITs. We further exclude stocks whose prices are below \$1 and above \$1,000. Finally, we exclude Schedule 13D/A filings (i.e., amendments to previously submitted filings) that are mistakenly classified as original Schedule 13D filings. Moreover, we exclude events during 1994 and 1995 because OptionMetrics coverage starts in 1996.

The final sample comprises the universe of all Schedule 13D filings that satisfy the above criteria from 1996 to 2010, which totals 2,905 events. During the sample period, on average 194 events take place each year. Importantly, our top-down approach guarantees that the sample contains *all* Schedule 13D filings with information on trades. The time series distribution of events is reported in the Appendix.

For each event we extract the following information from the Schedule 13D filings: the CUSIP of the underlying security, transaction date, transaction type (purchase or sell), transaction size, and transaction price. In addition, we extract the filing date, event date

⁵To quote from Item 5(c), filers have to “...describe any transactions in the class of securities reported on that were effected during the past sixty days or since the most recent filing of Schedule 13D, whichever is less...”

⁶See Collin-Dufresne and Fos (2015) for detailed description of the procedure.

(date on which the 5% threshold is crossed), and beneficial ownership of the Schedule 13D filer at the filing date. In the vast majority of cases transaction data are reported at a daily frequency. If the transaction data are at a higher-than-daily frequency, we aggregate them to the daily level. Specifically, for each day we calculate the total change in stock ownership and the average purchase price. The average price is the quantity-weighted average of transaction prices.

We compile additional data from several sources. Stock returns, volume, and prices come from the Center for Research in Security Prices (CRSP). Intraday transactions data (trades and quotes) come from the Trade and Quote (TAQ) database. Daily data on prices and trading volume of exchange-traded options as well as their implied volatilities come from OptionMetrics. Order imbalance data for exchange traded options are provided by the International Securities Exchange. These data start in 2005. See Muravyev (2015) for further details. Table A1 defines all variables and Table A2 in the Appendix reports summary statistics of all variables.

II. Stock Prices and Realized Volatility around the Filing Date

In this section we document changes in stock prices and realized volatility around the filing date. On the filing date it becomes common knowledge that an activist shareholder has accumulated a significant position in the company and has an intention to influence the company's management.

Panel A in Figure 1 plots the average buy-and-hold return, in excess of the buy-and-hold return on the value-weighted NYSE/Amex/NASDAQ index from CRSP, from 50 days prior to the filing date to 40 days afterward. As can be seen, there is a run-up of about 2% from 50 days to one day prior to the filing date. The two-day jump in excess return observed at the filing date is around 2.5%. After that the excess return remains positive for about 10 days and cumulates to a total of 5.5%. Thus, the stock market reaction

to Schedule 13D filings is favorable (see also Brav et al., 2008; Klein and Zur, 2009; Collin-Dufresne and Fos, 2015).⁷

[Insert Figure 1 here]

Note that Schedule 13D filers trade on long-lived information that, by its very nature, is not likely to be available to other market participants. In most cases, these activist shareholders know they can increase the value of the firm they invest in by their own effort (e.g., shareholder activism). Their effort level is, of course, conditional on their achieving a large stake in the firm. It is their very actions and shareholding that constitute the “private” information in such cases. Only when they file with the SEC, at most 10 days after their holdings reach the 5% threshold, does the information become public. The extent to which the market believes their future actions have value over and above what is already impounded in prices can be measured using announcement returns. The evidence reported in Panel A of Figure 1 strongly supports the assumption that Schedule 13D filers possess valuable information on the underlying securities when they trade in the pre-announcement period.⁸

We next investigate changes in realized volatility around the filing date. The realized volatility is calculated as the absolute value of daily stock return (and for robustness we also computed realized volatility measures from intra-day data). The results are reported in Panel B of Figure 1, which plots the realized volatility from 50 days before the filing date to 50 days after. The dark (gray) line plots the realized volatility for the sample of event (matched) stocks. Matched stocks are assigned based on the same

⁷Collin-Dufresne and Fos (2015) show that the excess return around Schedule 13D filings is not only positive, but also statistically significant.

⁸In addition to the average buy-and-hold return, we follow Collin-Dufresne and Fos (2015) and analyze profits made by Schedule 13D filers on purchasing stocks at the pre-announcement prices. The results are reported in Table A3 in the Appendix and suggest that Schedule 13D filers make significant profits. For example, a Schedule 13D filer who acquires a \$62 million stake in a \$874 million market cap company (i.e., a 7.14% stake, which is the average stake size in our sample) expects to benefit \$2.35 million.

industry, exchange, and market cap. We find that the realized volatility is about 47% prior to the filing date. It jumps up on the filing date to 52% on the filing date (when the event becomes common knowledge), corresponding to an 11% increase. After the filing date the realized volatility decreases to about 44%. Figure A2 in the Appendix shows that there is a similar pattern of realized volatility around the filing date in the full sample of Schedule 13D filings (i.e., when we remove the requirement of target stocks having listed options).

Table I confirms the pattern we observe in Figure 1. Whereas the realized volatility measures increase insignificantly for the sample of matched stocks, there is a substantial reduction in these measures for the sample of event firms. For example, the realized volatility calculated using intra-day data decreases from 0.47 to 0.43 around the filing date, corresponding to a 9% reduction. When we consider the difference in changes of realized volatility between event and matched stocks, we find very similar results. The difference-in-differences estimates are negative and highly significant statistically. Overall, the evidence shows that the realized volatility drops after the filing date.⁹

[Insert Table I here]

The evidence indicate that there are two types of valuable private information revealed on the filing date. First, the excess return from 50 days prior to the filing date to 10 days after the filing date is positive and cumulates to a total of 6.5%. Thus, there is ‘directional’ private information. Panel A in Figure 1 shows that excess returns on event stocks are positive prior to the filing date. Specifically, about half of the directional private information is reflected in stock prices prior to the filing date. Thus, directional private information is reflected in stock prices. Moreover, Collin-Dufresne

⁹Realized volatility can drop for several reasons. First, activist shareholders can promote changes in corporate policies that lead to less uncertainty about future stock performance. Second, volatility can drop if the trading patterns of market participants change after the filing date. For instance, uninformed traders could avoid stocks with heavy presence of activist shareholders. We leave studying channels that lead to the volatility drop for future research.

and Fos (2015) show that directional information flows into stock prices when Schedule 13D filers purchases shares.

Importantly, the results reveal a novel empirical regularity about Schedule 13D filings: the realized volatility decreases around the filing. Specifically, the realized volatility decreases by about 10% after the filing date if we exclude the announcement day return (and about 20% if we include it). This is consistent with the presence of private information about volatility. We next investigate whether option markets reflect that private information *prior* to Schedule 13D filing dates.

III. Does volatility information flow into option prices?

In this section we investigate whether private information is incorporated into *option* prices. Whereas informed traders can potentially trade on directional information in either stock or option markets, they can only trade on volatility information in non-linear securities such as options.

Panel A in Figure 2 shows both the *future* 30-day realized volatility and the 30-day implied volatility from option prices. Both volatilities decrease in lock-step starting 30 days prior to the filing date. Clearly, the average implied volatility closely tracks the average *future* realized volatility on our target firms around the filing date. Further evidence that implied volatilities are efficiently predicting future realized volatility can be gleaned by considering the profitability of a trading strategy that would sell delta-hedged option straddles to benefit from the future drop in realized volatility around the filing date. Such a strategy would earn an average excess return pre t-cost of 5.5% during the 30 days pre-filing, which would be dwarfed by the option bid-ask spread (around 8%) and stock transaction costs (see Figure A3 in the appendix).

[Insert Figure 2 here]

To further investigate the relation between implied and future realized volatilities, we test whether the predictability holds when we condition on future changes in realized volatility. Specifically, we consider three sub-samples: (1) events with large drops in realized volatility around filing date, (2) events with small changes in realized volatility around filing date, and (3) events with an increase in realized volatility around filing date. Figure 3 reports the results. The results again clearly indicate that even *conditionally* implied volatility predicts future realized volatility.

[Insert Figure 3 here]

We next ask whether option prices reflect the timing and the size of the informational event. To address this question, we plot changes in time slope around the filing date. Time slope is defined as the ratio of implied volatilities for call options with 30 days to expiration and call options with 365 days to expiration, minus one. Panel B in Figure 2 presents the results and shows that the ratio between short-term and long-term implied volatilities increases closer to the filing date. This evidence suggests that option prices reflect a higher chance of an informational event in the short term relative to the long term.

To further investigate whether option prices reflect higher chances of a large stock price move, we next investigate implied volatility skews. Panels C and D of Figure 2 plot Put and Call options implied volatility skews around the filing date. Put skew is defined as the ratio of implied volatilities for out-of-the-money and at-the-money put options, minus one. We find that put skew increases substantially closer to the filing date. In contrast, there is no change in put skew for the sample of matched stocks. Call skew is defined as the ratio of implied volatilities for out-of-the-money and at-the-money call options, minus one. Similarly to the results for put options, we find that call skew increases substantially closer to the filing date for our target stocks, but that there is no change in call skews for the sample of matched stocks.

Overall, option prices reflect higher chances of a substantial stock price movement closer to the filing date. Table II confirms the pattern we observe in Figure 2. In this table we compare differences in changes of outcome variables from $(t-60,t-31)$ days prior to the filing date t to $(t-30,t-1)$ days prior to the filing date between event and matched stocks.

[Insert Table II here]

First, consider changes in option market outcomes closer to the filing date. We analyze put skew, call skew, time slope, implied volatility of call options, changes in implied volatility of call options, implied volatility of put options, and changes in implied volatility of put options. Panel A in Table II reports the results. Confirming patterns documented in Figure 2, we find significant increases in put skew, call skew, and time slope as well as significantly lower levels of implied volatilities closer to the filing date. Thus, option prices change substantially closer to the filing date. Specifically, changes in implied volatilities reflect higher chances of an informational event and changes in time slope of implied volatilities indicate that market participants anticipate the timing of the event.¹⁰

Overall, the evidence indicates that volatility private information flows into option prices. In the next section we analyze *how* that information flows into option prices.

IV. How does private information flow into prices?

In this section we study the role of informed trading in price discovery using the information on Scheduler 13D filers' trades in both stock and option markets.

¹⁰We also consider changes in stock market outcomes closer to the filing date. We follow Collin-Dufresne and Fos (2015) and analyze excess return, volatility, volume, and bid-ask spread. Consistently with Collin-Dufresne and Fos (2015), we find that changes in excess returns are higher for event stocks relative to matched stocks. This is consistent with the evidence reported in Figure 1. We also find that volatility (insignificantly) decreases and trading volume increases closer to the filing date.

A. Hypotheses

We begin from describing potential channels through which volatility private information could flow into option prices. First, the information could flow through activist's trades in the option market. This leads to the following hypothesis.

Hypothesis 1 (Informed trading in options). *Scheduler 13D filers trade options with an intention to benefit on volatility private information. When Scheduler 13D filers trade options, implied volatility decreases, skew and time-slope increase, and option bid-ask spread increases.*

The information could also flow through activist's trades in the stock market. This leads to the following hypothesis.

Hypothesis 2 (Informed trading in stocks). *Scheduler 13D filers trade stocks with an intention to benefit on directional private information. When Scheduler 13D filers trade stocks, implied volatility decreases, skew and time-slope increase, and option bid-ask spread increases. The results are stronger when the level of integration between stock and option markets is high.*

To differentiate between these two hypotheses, one needs to observe were informed investors trade. Whereas in general market participants and researchers do not know whether informed trading is taking place, the unique feature of our data set allows us to know (i) whether Scheduler 13D filers traded options and/or stocks, (ii) activists' positions in options and stocks, and (iii) days when informed investors trade and days when they do not trade. We next explore our data to shed light on the channel through which volatility private information flows into option prices.

B. When do activists use derivatives?

How often do activists use derivatives? To address this question, we manually check all Schedule 13D filings in our sample for information on any type of derivatives. We

find that activists do not disclose any information on derivatives in the vast majority of Schedule 13D filings. Specifically, we could find information on derivatives only in 66 Schedule 13D filings, corresponding to 2.27% of the sample. Given the broad formulation of disclosure requirement in Item 6 (see Section I), the evidence indicates that activists rarely participate in derivatives transactions. An alternative explanation is that activists are using derivatives without disclosing them. This seems unlikely however, since in this case they are clearly violating the SEC disclosure requirements.

One possibility is that activists do not use derivatives because these securities are not available or are too illiquid. To investigate this conjecture, we check for how many Schedule 13D filings targets have exchange-traded options. For every event, we calculate the number of days with positive option trading volume during 80-day period prior to the filing date. For each event, we set ‘Options available’ indicator to one if the number of days with days with positive option trading volume exceeds 40, and zero otherwise.

Indeed, we find that exchange-traded options are available in 580 events, corresponding to 20% of the events.¹¹ When exchange-traded options are available, the probability that an activist uses derivatives (including OTC) is 10%. In contrast, when exchange-traded options are not available, the probability that the activist discloses information on derivatives decreases to 0.34%. Thus, the availability of exchange-traded options is a strong predictor of the usage of derivatives by activists. Overall, the evidence indicate that in the vast majority of cases Schedule 13D filers do not use derivatives. In the Internet Appendix we provide further evidence on characteristics of firms that use derivatives to characteristics of firms that do not use derivatives.

C. How Do Activists Use Derivatives?

Schedule 13D filers disclosed the usage of derivatives in 66 cases. Table III characterizes the usage of derivatives in the full sample (column (1)), in the sample with listed options

¹¹Mayhew and Mihov (2004) study factors influencing the selection of stocks for option listing.

(column (2)), and in the sample of events in which activists indicated the usage of OTC derivatives (column (3)).

[Insert Table III here]

Full-sample results reveal that activists seek a ‘long’ stock price exposure in most of events. Specifically, activists hold long call (short put) positions in 84.8% (36.4%) of events. The activists have both long call and short put positions in 24.2% of events. Further, the activists have long equity swap positions in 10.6% of events. Either short call positions or long put positions are rare. In less than 2% of events activists had no long exposure through positions in derivatives. Overall, the evidence indicates that the main driving force behind the usage of derivatives by Schedule 13D filers is achieving positive exposure to targets’ stock prices. This result is not consistent with the notion that Schedule 13D filers use derivatives to decouple economic and voting exposure to their targets (Hu and Black, 2007).

When we consider what fraction of activists’ beneficial ownership is in derivatives, we find that activists hold on average 6.4% of outstanding common stock in direct stock ownership. In addition, activists hold 2.3% of outstanding common stock through derivatives positions. Thus, activists achieve more than 25% of the economic exposure through derivatives. We also find that when activists use derivatives, 87.9% of targets have listed stock options and in 42.4% of events activists use over-the-counter derivatives, suggesting that exchange-listed options are not necessary for the activists to achieve exposure through derivatives.

When we relate this result to the percentage of outstanding shares held by activists in cases when activists do not use derivatives, we find that when activists use derivatives they hold a larger proportion of outstanding shares. Specifically, activists hold 7.5% of outstanding shares when no information on derivatives is disclosed (see Collin-Dufresne and Fos, 2015), which is lower than 8.7% reported in the sample of events with

information on derivatives (6.4% in direct stock ownership plus 2.3% of outstanding common stock through derivatives positions).

When we compare the full sample results to results in the sub-sample of events with listed options, we find little difference in the way the activists use derivatives. In contrast, we find that activists use derivatives more aggressively when they use over-the-counter derivatives. For instance, activists' exposure through derivatives increases from 2.3% in the full sample to 4.0% when they use over-the-counter derivatives. Similarly, activists are more likely to seek long exposure in this sub-sample: incidences on long call positions and short put positions are more likely in this sub-sample.

D. The Role of Informed Trading

In this section we provide evidence based on Schedule 13D filers' trades in option and stock markets. We estimate the following regression:

$$y_{it} = \gamma_1 itrade_{it} + \gamma_2 itrade_opt_{it} + \gamma_3 itrade_{it} * itrade_opt_{it} + \eta_i + X'_t \gamma_4 + \epsilon_{it}, \quad (1)$$

where y_{it} is a measure of trading activity for company i on day t minus a measure of trading activity for a matched stock, $itrade$ indicates days on which Schedule 13D filers trade the stock, $itrade_opt$ indicates days on which Schedule 13D filers trade options, X is a vector of control variables (four Fama-French factors and VIX), and η_i are event fixed effects. The interaction term captures days when Schedule 13D filers trade in stock and derivatives markets. The results are reported in Table IV.

[Insert Table IV here]

First, we compare implied volatility measures on days when Schedule 13D filers trade stocks and on days when Schedule 13D filers do not trade stocks ($itrade$). The results are reported in Panel A of Table IV and suggest that changes in outcome variables are larger

on days when Schedule 13D filers trade stocks than on days when Schedule 13D filers do not trade stocks. Specifically, put and call implied volatility skew measures increase, time slope increases, and put and call implied volatilities decrease when Schedule 13D filers trade stocks. Thus, more information flows into *option* prices on days when Schedule 13D filers trade in the stock market. When we consider days when Schedule 13D filers trade in the option market (*itrade_opt*), we find no significant changes in implied volatility when Schedule 13D filers trade derivatives, which is consistent with the activists' trades in the option market not carrying incremental volatility information. Interestingly, both put and call implied volatilities are higher on days when Schedule 13D filers trade stocks and options ($itrade * itrade_opt$).

Next, we consider the relation between Schedule 13D filers' trades and option market bid-ask spreads. The results are reported in Panel B of Table IV. We find that option bid-ask spreads are wider when Schedule 13D filers trade in the underlying shares. In contrast, *itrade_opt* indicates that there are no significant changes in option market bid-ask spreads when Schedule 13D filers trade derivatives. The results are robust across different types of options and regression specifications. The positive relation between option market bid-ask spreads and trades by Schedule 13D filers in the stock market suggests that option market makers price the increase in adverse selection risk on days when Schedule 13D filers trade stocks.

To further understand how the information flows into option prices, we study trading activity in the option market. Specifically, we look at option volume, put volume, call volume, and option order imbalance measures. The results are reported in Panels C and D of Table IV. We find that on days when Schedule 13D filers trade in the stock market, there is an insignificant decrease in option volume. When we consider changes in trading volume for put and call options, we find that whereas call volume is lower closer to filing days, there is no significant difference between call volumes on days when Schedule 13D filers trade and days when they do not trade. In contrast, when we consider

trading activity in put options, we find that put volume is significantly higher on days when Schedule 13D filers trade in the stock market. Therefore, whereas it is not likely that changes in call option prices are driven by abnormal trading activity, it remains a possibility that information flows into prices of put options through trading.

Option volume has little to say about trade direction, i.e. whether investors buy or sell options. To explore this dimension we analyze option order imbalance. Following the literature, order imbalance is computed as the difference between the number of buy and sell-initiated option trades by non-market-makers divided by total number of option trades for a given stock and day. Order imbalances for a sub-sample of options (such as only calls) or trades (such as trades that open new position) are defined similarly. Thus, order imbalance can range only between -1 and 1. Our data identifies who (market-maker or non market-maker) takes each side of option transaction and are aggregated at the option contract by day level. Muravyev (2015) describes the data and order imbalance measures in detail. We consider the total order imbalance and the order imbalance for trades when a new option contract is opened.

Panel D shows, however, that measures of order imbalance on days when Schedule 13D filers trade stocks are not statistically different from measures of order imbalance on days when Schedule 13D filers do not trade stocks (*itrade*). Similarly, measures of order imbalance on days when Schedule 13D filers trade derivatives are not statistically different from measures of order imbalance on days when Schedule 13D filers do not trade derivatives (*itrade_opt*). Interestingly, we find that order imbalance measures are significantly larger on days when Schedule 13D filers trade both stocks and derivatives (*itrade * itrade_opt*). Further, the results are stronger when open trades are concerned. Overall, Schedule 13D filers appear to have an impact on order imbalance measures when they trade in both stock and derivatives.

Finally, we describe the relation between Schedule 13D filers' trades in stock market (*itrade*) and stock market activity measures. We compare the market-adjusted returns,

bid-ask spread, volatility, and trading volume on days when Schedule 13D filers trade and on days when Schedule 13D filers do not trade during the 60-day disclosure period. The evidence is consistent with trades by Schedule 13D filers affecting stock prices. Consistently with the evidence documented by Collin-Dufresne and Fos (2015), market-adjusted returns (*eret*) are higher by 0.18% on days when Schedule 13D filers trade. Thus, the evidence indicates that on days when Schedule 13D filers trade, prices move in the ‘right’ direction. Even though they have significant private information (as evidenced by the abnormal profits they generate) we find that, on days when Schedule 13D traders trade stocks, bid-ask spreads are lower and trading volume is higher. These results are consistent with Collin-Dufresne and Fos (2016), who predict that informed traders should select to trade when noise trading activity is large and when price impact is smaller. Finally, we find that the realized volatility is (insignificantly) higher on days when Schedule 13D filers trade, which is also consistent with more information being incorporated in prices on those days.

We next consider days when Schedule 13D filers trade derivatives (*itrade_opt*). We find that the market-adjusted returns, volatility, and trading volume are higher on days when Schedule 13D filers trade options. For example, the market-adjusted returns are higher by 0.52% on days when Schedule 13D filers trade derivatives. When also find that stock bid-ask spreads are higher on days when Schedule 13D filers trade stocks and derivatives (*itrade * itrade_opt*). This result is consistent with less strategic and more aggressive trading on those days. This could be driven by Schedule 13D filers’ derivatives counterparties hedging their positions in the stock market, for example.

As we discussed in Section I, whereas Schedule 13D filers have to disclose whether they have used derivatives, the precision of the disclosed information is vaguely specified. For example, Schedule 13D filers do not have to disclose on what days they traded derivatives. To avoid any selection bias induced by voluntary disclosure of information, hereafter we drop events when activists use derivatives. It leaves us with 522 Schedule 13D filings.

A unique feature of this sample is that we know not only when informed activists trade in the underlying shares, but also that they do not participate in direct trading in derivatives. Thus, if we detect an impact of informed stock trading on option markets, this cannot be due to the direct effect of informed order flow in options, but rather must be due to an indirect channel, e.g., to option traders reacting to the information revealed by the trading activity in the stock market.

If option market participants infer information from sources unrelated to Schedule 13D filers' trades, then changes in implied volatilities should be similar on days when Schedule 13D filers trade and on days when Schedule 13D filers do not trade. In contrast, if option market participants infer information from sources directly related to Schedule 13D filers' trades in the stock market, the changes in implied volatilities should be larger on days when Schedule 13D filers trade than on days when Schedule 13D filers do not trade. We estimate the following regression:

$$y_{it} = \gamma_1 itrade_{it} + X_t' \gamma_2 + \eta_i + \epsilon_{it}, \quad (2)$$

where y_{it} is a measure of trading activity for company i on day t , $itrade$ indicates days on which Schedule 13D filers trade in stock market, X is a vector of control variables (four Fama-French factors and VIX), and η_i are event fixed effects. Results are reported in Table V.

[Insert Table V here]

Overall, the results show that much of the changes in implied volatilities and in option bid-ask spreads happen on days when informed schedule 13D filers trade in the underlying equity market and even though they do not trade any derivatives. This evidence is consistent with option market participants inferring information about future stock volatility from the price and volume activity in the stock market.

What explain the opposite results for stock and option bid-ask spreads? Because Schedule 13D filers select to trade based on stock market activity and not based on option market activity, option market bid-ask spreads reveal higher adverse selection risk (Collin-Dufresne and Fos, 2015).

So far, the evidence indicates that directional as well as volatility information flows into prices. When it happens, option bid-ask spreads increase. We next investigate whether this increase in bid-ask spreads reflects increased adverse-selection risk due to directional or to volatility information.

To capture differences in directional information, we split the sample based on the average buy-and-hold return around the filing date in excess of the buy-and-hold return of the value-weighted market from 30 days prior to the filing date to 1 day afterwards. To capture differences in volatility information, we split the sample based on the difference in realized volatility during $(t+2,t+6)$ and the remaining sample period. For each subsample we report the observed change in bid-ask spreads. Panel A in Table VI reports the results.

[Insert Table VI here]

Consider the first row of the table. Both in the high and low buy and hold return subsamples, the difference-in-differences estimate for the change in option bid-ask is positive and economically significant. The evidence shows that the increase in option bid-ask spreads is independent of the magnitude of the directional information. Whereas the point estimate is slightly larger in the high than in the low buy-and-hold return subsample (0.30% versus 0.23%), the difference is not statistically significant. In contrast, column (1) shows that option bid-ask spreads are wider only when the volatility drop is large. The difference-in-differences estimate is 0.49% when the volatility drop is large (highly statistically significant) versus 0.04% when the volatility drop is small (statistically insignificant). Overall, the results are consistent with volatility private

information playing the key role in the increase in option bid-ask spreads closer to the filing date.

Panels B and C of Table VI show that changes in option market trading activity are also related to the type of private information. Specifically, we find a significant decrease in option trading volume when the magnitude of the volatility information is large. In contrast, the magnitude of the directional information is not associated with changes in option trading volume. Further, Panel C reveals that the results are stronger for call option trading volume (the results for put options are insignificant).

Overall, the evidence indicates that option market bid-ask spreads increase and trading volume decreases substantially when volatility private information is large. This is consistent with market makers perceiving higher adverse selection risk associated with the volatility component of private information.

V. Conclusion

In this paper we use a novel data set of trades by investors who we can identify as having substantial private information to study how private information flows into stock and option prices. We find that Schedule 13D filers trades contain information about both the direction and the volatility of future stock returns. We find that both types of information are reflected in stock and option prices prior to Schedule 13D filing days. Option markets reflect the adverse selection risk associated with the volatility component of private information rather than the directional component.

We find that this class of informed investors rarely use derivatives. They trade little in derivatives (2.2%), but more (10%) when listed option markets are available. Schedule 13D filers use derivatives to leverage up their position in stocks and reduce the cost of the HSR disclosure rule. Interestingly, even when informed investors do not trade in derivatives, option markets seem to respond to their trades in the stock market. On

days when they trade in stocks, realized volatility increases, implied volatilities decrease, bid-ask spreads in options widen, and put volume increases.

(a) BHAR in excess of the buy-and-hold return of the market.

(b) Realized volatility.

Figure 1
Stock Return and Volatility around the filing date. In Panel A the solid line plots the average buy-and-hold stock return around the filing date in excess of the buy-and-hold return of the value-weighted market from 50 days prior to the filing date to 40 days afterwards. Panel B plots the realized volatility from 50 days before the filing date to 50 days after. The realized volatility is defined in Table A1. The dark (gray) line plots the realized volatility for the sample of event (matched) stocks. Matched stocks are assigned based on the same industry, exchange, and market cap. The filing date is the day on which the Schedule 13D filing is submitted to the SEC. The sample covers 580 Schedule 13D filings in which there are listed options on target firms.

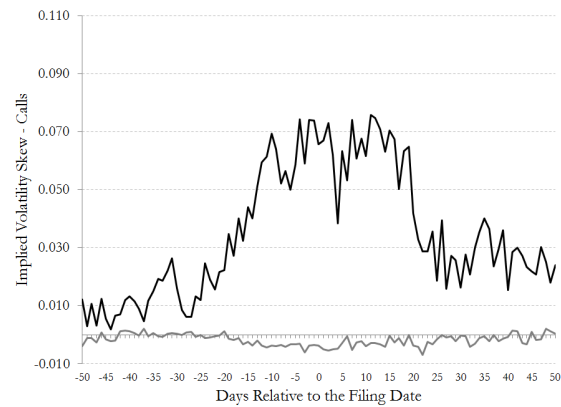

(a) Expected realized and implied volatilities

(b) Time slope

(c) Put options implied volatility skew

(d) Call options implied volatility skew

Figure 2

Option implied volatility. In Panel A the dark line plots the average realized volatility over the next month from 50 days before the filing date to 50 days after. The dashed line plots implied volatilities of at-the-money options with one month till expiration. In Panel B the dark (gray) line plots the time slope for the sample event (matched) stocks from 50 days before the filing date to 50 days after. In Panels C and D the dark (gray) line plots put and call skew for the sample event (matched) stocks from 50 days before the filing date to 50 days after. All outcome variables are defined in Table A1. The sample covers 580 Schedule 13D filings in which there are listed options on target firms. Matched stocks are assigned based on the same industry, exchange, and market cap.

(a) Events with large drop in realized volatility. (b) Events with small change in realized volatility.

(c) Events with an increase in realized volatility.

Figure 3

Implied and future realized volatilities: conditional results. Dark lines plot the average realized volatility over the next month from 50 days before the filing date to 50 days after. Dashed lines plot implied volatilities of at-the-money options with one month till expiration. In Panel A the sample is restricted to events with large decrease in realized volatility around the filing date. In Panel B the sample is restricted to events with small change in realized volatility around the filing date. In Panel C the sample is restricted to events with an increase in realized volatility around the filing date. All outcome variables are defined in Table A1. The sample covers 580 Schedule 13D filings in which there are listed options on target firms.

Table I

Realized volatility around the filing date. This table compares the level of annualized realized volatility before and after the filing date. The realized volatility is defined in Table A1. The sample covers 580 Schedule 13D filings in which there are listed options on target firms. Column (1) reports the average level of realized volatility for 50 days that precede the filing date. Column (2) reports the average level of realized volatility for 50 days after the filing date. Column (3) reports the average change in realized volatility around the filing date and the t -stat of the difference. Columns (4) to (6) repeat the analysis for the sample of matched stocks. Matched stocks are assigned based on the same industry, exchange, and market cap. Column (7) reports the average difference-in-difference in the realized volatility and the t -stat of the difference. *** indicates statistical significance at the 1% level.

	Event stocks			Matched stocks			
	Before (1)	After (2)	Difference (3)	Before (4)	After (5)	Difference (6)	Diff-in-diff (7)
Realized volatility (daily)	0.4075***	0.3687***	-0.0388*** [-3.75]	0.4281***	0.4353***	0.0072 [0.88]	-0.0460*** [-3.49]

Over-the-counter	0.424	0.345	1.000

Table IV

The flow of information into prices and informed trading. This table compares the outcome variables on days when Schedule 13D filers trade and on days when Schedule 13D filers do not trade. All outcome variables are defined in Table A1. The table reports estimates of γ_1 , γ_2 , and γ_3 from regression (1): $y_{it} = \gamma_1 \text{itrade}_{it} + \gamma_2 \text{itrade_opt}_{it} + \gamma_3 \text{itrade}_{it} * \text{itrade_opt}_{it} + \eta_i + X_t' \gamma_4 + \epsilon_{it}$, where y_{it} is a measure of trading activity for company i on day t minus a measure of trading activity for the matched stock, itrade indicates days on which Schedule 13D filers trade in stock market, itrade_opt indicates days on which Schedule 13D filers trade in option market, X is a vector of control variables (four Fama-French factors and VIX), and η_i are event fixed effects. Matched stocks are assigned based on the same industry, exchange, and market cap. The sample covers 580 Schedule 13D filings in which there are listed options on target firms and covers $(t-1, t-60)$ period before the filing date. Heteroskedasticity-robust standard errors are clustered at the event level. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table V**The flow of information into prices and informed trading: No derivatives are used.**

This table compares the outcome variables on days when Schedule 13D filers trade and on days when Schedule 13D filers do not trade. All outcome variables are defined in Table A1. The table reports estimates of γ_1 from regression (2): $y_{it} = \gamma_1 \text{itrade}_{it} + \eta_i + X_t' \gamma_3 + \epsilon_{it}$, where y_{it} is a measure of trading activity for company i on day t minus a measure of trading activity for the matched stock, itrade indicates days on which Schedule 13D filers trade in stock market, X is a vector of control variables (four Fama-French factors and VIX), and η_i are event fixed effects. Matched stocks are assigned based on the same industry, exchange, and market cap. The sample covers 522 Schedule 13D filings in which there are listed options on target firms but Schedule 13D filers do not use any type of derivatives and covers ($t-1, t-60$) period before the filing date. Heteroskedasticity-robust standard errors are clustered at the event level. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table VI

Option market bid-ask spread, volume, and information type. This table presents the relation between changes in option market bid-ask spread and volume reported in Table II and types of private information. CAR is the average buy-and-hold return around the filing date in excess of the buy-and-hold return of the value-weighted market from 30 days prior to the filing date to 1 day afterwards. It measures the magnitude of directional private information. Column (1) reports results for all values of CAR. Column (2) reports results when CAR is below median. Column (3) reports results when CAR is above median. Column (4) reports the difference between estimates in columns (3) and (2). Volatility drop is the difference in realized volatility during $(t+2,t+6)$ and the remaining sample period. It measures the magnitude of volatility private information. The first row reports results for all values of volatility drop. The second row reports results when volatility drop is above median. The third row reports results when volatility drop is below median. The fourth row reports the difference between estimates in the second and the third rows. Panel A reports the results for option market bid-ask spread. Panel B reports the results for option market volume. Panel C reports the results for call options volume. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix for
“Informed Trading and Option Prices: Evidence from Activist Trading”

Figure A1
Time distribution of Schedule 13D filings. This chart plots the number of Schedule 13D filings that satisfy the criteria listed in Section I. The dark bars represent Schedule 13D filings with no information on derivatives. The gray bars represent Schedule 13D filings with information on derivatives.

(a) Full sample

(b) Sample with listed options

Figure A2

Realized volatility around filing date. Dark lines plot the realized volatility from 50 days before the filing date to 50 days after. The realized volatility is defined in Table A1. The filing date is the day on which the Schedule 13D filing is submitted to the SEC. Panel A plots the realized volatility in the full sample of 2,905 Schedule 13D filings. Panel B plots the realized volatility in the sample of 580 Schedule 13D filings in which there are listed options on target firms.

Figure A3

Buy-and-hold return on selling delta-neutral option strategies. The solid line plots the average buy-and-hold return on selling delta-neutral option strategies, in excess of the average buy-and-hold return on selling delta-neutral option strategies for matched stocks, from 50 days prior to the filing date to 5 days prior to the filing date. The strategy for betting on a drop in volatility is to sell options (both calls and puts) that are close to at-the-money (their prices are most sensitive to volatility information) and then (delta) hedges them by trading the underlying stock (making it immune to small directional changes in the stock price). The portfolio is revised daily. The filing date is the day on which the Schedule 13D filing is submitted to the SEC. The sample covers 580 Schedule 13D filings in which there are listed options on target firms.

Table A1
Variable definitions.

Panel A. Stock market variables	
Excess Return	Stock return in excess of the CRSP value-weighted return.
Volatility	Volatility of daily stock returns.
Realized Vol	Realized volatility based on the absolute value of daily stock return.
Intraday Realized Vol	Computed from the sum of squared 5-minute returns over a trading day. The returns are computed from the TAQ trade transaction data.
Bid-Ask Spread	The percentage spread, calculated using daily close ask and bid.
Volume	Daily trading volume.
Panel B. Option market variables	
IV	Implied volatility provided by OptionMetrics; calculated based on 30 days to expiration.
Skew	The ratio of implied volatilities for out-of-the-money and at-the-money options, minus one. A put option is out-of-the-money (at-the-money) if delta is -0.3 (-0.5). A call option is out-of-the-money (at-the-money) if delta is 0.3 (0.5).
Time slope	The ratio of implied volatilities for call options with 30 days to expiration and call options with 365 days to expiration, minus one.
Spread, %	The percentage spread, calculated using daily close ask and bid.
Order Imbalance	The difference in the proportion of buy- and sell-initiated trades.
Panel C. Firm characteristics (firm-year level)	
Options available	Equals one if exchange traded options are available.
Market cap	Market capitalization.
Illiquidity	Amihud (2002) illiquidity measure, defined as the yearly average (using daily data) of $1000 \sqrt{\frac{ Return }{DollarTradingVolume}}$.
BM	The ratio of the book value of equity to the market value of equity.
Analyst	The number of analysts covering the stock.
Stock return	12-month buy-and-hold return.
INST	The proportion of shares held by institutions.
INST AHF	The proportion of shares held by activist hedge funds. Data on activist hedge funds are from Brav et al. (2008).
HSR	Equals one when a 5% toehold meets the “Size-of-Transaction Test” specified by the HSR Act.

Table A2

Summary statistics. Panel A reports summary statistics for stock market variables. Panel B reports summary statistics for option market variables. Panel C reports summary statistics for firm characteristics. All potentially unbounded variables are pre-winsorized at the 1% and 99% extremes. Columns (1) and (2) report the mean and standard deviation of each variable. Columns (3)–(9) report their values at the 1st, 5th, 25th, 50th, 75th, 95th, and 99th percentiles.

Variable Name	Mean (1)	SD (2)	1% (3)	5% (4)	25% (5)	50% (6)	75% (7)	95% (8)	99% (9)

Table A3

Profits from Informed Trades. This table presents summary statistics for three measures of profits. *Trading Profit* is defined as $\mathbf{q}'(p_{post} - \mathbf{p})$, where \mathbf{q} is the vector of trades (purchases are positive and sales are negative), p_{post} is the post-announcement price, and \mathbf{p} is the vector of transaction prices. The post-announcement price is the average price during the week that follows the filing date. *Total Profit* is defined as $Trading\ Profit + (p_{post} - p_0)w_0$, where p_0 is the price of the first transaction disclosed in the Schedule 13D filing and w_0 is the initial ownership, established prior to the first transaction disclosed in the Schedule 13D filing. *Value Created* is defined as $(p_{post} - p_0)SHOUT$, where *SHOUT* is the number of shares outstanding. The sample covers 580 Schedule 13D filings in which there are listed options on target firms. Average measures of profits as well as *t*-statistics are reported for five Market CAP quantiles, where Market CAP is the market capitalization of the targeted company. ** and *** indicate statistical significance at the 5% and 1% levels, respectively.

Market CAP Quantile	Market CAP (1)	Trading Profit (2)	Total Profit (3)	Value Created (4)
Q1 - low	214,795,218	(15,119) [-0.09]	52,892 [0.16]	(2,224,586) [-0.35]
Q2	438,976,302	1,011,851*** [3.56]	1,850,709*** [2.75]	25,966,410** [2.55]

Q5 - high	3,916,358,736	2,675,665*** [4.95]	3,720,508** [2.52]	53,740,776* [1.87]

A. When do activists use derivatives? - Additional results

To further investigate when activists are more likely to use derivatives, we next compare characteristics of firms that use derivatives to characteristics of firms that do not use derivatives. Results are reported in Table A4. Consistent with the previous result, the evidence in columns (1) to (4) shows that activists are more likely to use derivatives when targets have exchange-traded options: when activists (do not) use derivatives, 84% (21%) of targets (do not) have exchange-traded options.

[Insert Table A4 here]

Activists are also more likely to use derivatives when the targets' market capitalization is larger (on average it is three times larger than when activists do not use derivatives). Additional factors that are positively associated with the usage of derivatives are high stock liquidity, large number of analysts covering the stock, low book-to-market ratio, and high institutional and activist ownership.

We next test whether activists are more likely to use derivatives when a 5% toehold in the target company meets the “Size-of-Transaction Test” specified by the Hart-Scott-Rodino (HSR) Act of 1976. The HSR Act requires parties to file notifications with the Federal Trade Commission, Department of Justice, and the *firm* when a proposed transaction—such as a merger, joint venture, stock or asset acquisition, or exclusive license—meets specified thresholds and no exemptions apply.¹² If a notification is

¹²A filing is required if the parties meet both the “size of person” and “size of transaction” thresholds. Size-of-Person Test is met if one party to the transaction has \$152.5 million or more in annual sales or total assets and the other has \$15.3 million or more in annual sales or total assets. If the acquired party is not engaged in manufacturing, the test is slightly different: while one party must meet the \$15.3 million test and the other party must meet the \$152.5 million test, in addition the acquired company must have \$15.3 million of assets or \$152.5 million of revenues. Size-of-Transaction Test is met if, as a result of the transaction, the buyer will acquire or hold voting securities or assets of the seller, valued in excess of \$76.3 million. All information and materials provided in connection with a HSR filing are treated as confidential and will not be disclosed by the government to third parties. The materials are even exempt from Freedom of Information Act requests. However, if the activist's purchase of a

required, the transaction cannot close while the statutory waiting period runs and the agencies review the transaction. Activist shareholders fall into the group of investors that is required to issue such a notification. They view this filing requirement as costly. For instance, a prominent activist shareholder Bill Ackman referred to this filing requirement as follows: “The last thing you want to do is alert the target that you are going to buy a big stake in a company.”¹³

Derivative contracts can mitigate the cost of this filing. An activist shareholder can enter into a derivative contract that provides economic exposure with no direct ownership and therefore delay the HSR filing. Specifically, an activist can build economic exposure through derivative contracts, file Schedule 13D, and only then follow the HSR filing procedure to get approval to acquire the underlying shares. Thus, derivatives can delay the HSR filing until after the Schedule 13D filing is made. This way the notification is sent to all relevant parties after the activist’s intention is common knowledge.

To capture the effect of the HSR Act, we set “HSR” to indicate cases when a 5% toehold meets the “Size-of-Transaction Test” specified by the HSR Act. The evidence in Table A4 reveals that activists are more likely to use derivatives when crossing a 5% toehold meets the “Size-of-Transaction Test” specified by the HSR Act of 1976. Specifically, when activists (do not) use derivatives, 66% (18%) of targets have a 5% toehold that meets (does not meet) the “Size-of-Transaction Test” specified by the HSR Act. The results therefore confirm that activists are more likely to use derivatives when an equity-only 5% toehold would trigger the HSR Act filing.

Of course, several firm characteristics that are associated with the usage of derivatives might simply proxy for the availability of exchange-listed derivatives. For example, large

5% toehold triggers HSR filing requirement, the activist is required to notify the company about the intended transaction.

firms with high stock liquidity are more likely to have actively traded listed options. To address this possibility, we next compare characteristics of targets that use and do not use derivatives in the sub-sample of firms with available listed options. Results are reported in columns (5) to (8) of Table A4. Consistent with our prior, we find the several firm characteristics have weaker associations with the usage of derivatives in this sub-sample (e.g., institutional ownership, book-to-market ratio, and stock liquidity).

On the other hand, four firm characteristics—market cap, the number of analysts covering the stock, activist ownership, and the HSR Act dummy—continue to be positively and significantly associated with the usage of derivatives. For example, when activists (do not) use derivatives the average number of analysts covering the target is 11.75 (9.44). This difference corresponds to 25% increase in the number of analysts covering the target. Similarly, the average market cap is \$1,073m (\$690m) when activists do (do not) use derivatives.

We next consider option-market variables. Panel B in Table A4 reports the results. We find that activists are more likely to use derivatives when option markets are more liquid (bid-ask spreads are narrower). Moreover, we find that a higher put-to-call volume ratio is also positively associated with the usage of derivatives.

To conclude the analysis of firm characteristics that are associated with the usage of derivatives and, in particular to account for the fact that many significant variables uncovered above are likely to be correlated, we estimate a multivariate linear probability model to predict the usage of derivatives by Schedule 13D filers. The regressions are estimated using firm characteristics that are measured at the end of the fiscal year that precedes the Schedule 13D filing. Results are reported in Table A5.

[Insert Table A5 here]

We find that the availability of listed options, the HSR indicator, and activist ownership continue to be positively associated with the usage of derivatives. Perhaps surprisingly,

the table reveals that effects of market cap and stock illiquidity become insignificant after we augment the regression with the HSR indicator.

Table A4
When do activists use derivatives? This table presents characteristics of targets when activist use and do not use derivatives. Columns (1) to (4) report results for all Schedule 13D filing with available data on firm characteristics (2,466 events). Columns (5) to (8) report results for sub-sample with available listed options (580 events; see Section B for description of the “options available” criteria). Firm characteristics are measured at the end of the past fiscal year. Columns (1) and (5) report averages for targets when activist use derivatives. Columns (2) and (6) report averages for targets when activist do not use derivatives. Columns (3) and (7) report differences between (1) and (2) and (5) and (6) accordingly. Columns (4) and (8) report *t*-statistics of the differences. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table A5

When do activists use derivatives? Multivariate analysis. This table presents estimates of a linear probability model that predicts the usage of derivatives by Schedule 13D filers. Sample covers 2,021 Schedule 13D filings with available information on firm characteristics. Firm characteristics are measured at the end of the fiscal year that precedes the Schedule 13D filing. Table reports estimated coefficients and t -statistics. The t -statistics are calculated using heteroscedasticity robust standard errors. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.
